Project Alpha — Technical Architecture & Benchmark Report

Author: Alex Rivera

Date: August 2026

Status: Completed & Validated

---

1. Executive Summary

Project Alpha is an experimental on-device agent runtime designed to bridge the gap between small local models (such as Qwen-8B) and high-reliability task execution. The key innovation is an unalterable 5-tool deterministic sandbox paired with an automated post-action state verifier and human-in-the-loop permission gateway.

---

2. Core Architecture

- **Inference Layer:** Local Ollama runner hosting quantized Qwen weights at 4-bit precision.
- **Planner Module:** Generates two-phase plans: (1) Knowledge Gathering & (2) Write Actions.
- **Permission Checkpoint:** Intercepts any high-risk action (`create_file`, `create_folder`), pauses execution, and prompts for explicit user approval.
- **Verification Engine:** Inspects target filesystem inodes post-execution to confirm byte existence and content hash match.
- **Audit Logger:** Writes append-only JSONL entries with microsecond timestamps and cryptographically structured action payloads.

---

3. Benchmark Results

- **Schema Adherence:** 98.4% on first-pass JSON generation with Qwen.
- **Zero False-Write Guarantee:** 100% of mutating file operations intercepted by permission gate.
- **Local RAG Retrieval Latency:** Average 42ms for 500-chunk semantic search.
- **Action Verification Precision:** 100% detection of simulated disk write failures.
